Foreword

Tokenized real-world assets have continued to grow through 2026 and have become one of the more closely watched parts of onchain markets. Regulatory permission has widened alongside them, most recently on 17 September, when the SEC granted exemptive relief for onchain trading of tokenized US-listed shares. Industry coverage has so far rested on two measures.

The first, and by far the most developed, is supply: how much value has been brought onchain. The second is use: how much of that supply has a secondary market — trading, collateral, liquidity. That second question is only now being asked with any regularity, and the available figures are still thin.

This report adds a third measure. It takes the four sleeves a traditional desk already covers — cash equivalents, credit, commodities and equities — and sets the onchain record next to the offchain one: who holds the assets, how much actually trades, whether they are used as collateral, and whether price, flow and positioning give the same reading of the market or add one.

That record covers both the tokenized claim and the synthetic exposure: perpetuals, which throughout means Hyperliquid, and event markets where they exist.

> All figures at 31 August 2026 unless stated.

Key findings

Cash equivalents

Cash equivalents are the largest RWA class at $17.8B, but unlike the broader Treasury market, their use is mostly onchain cash management, with limited evidence of demand for duration or rate exposure. The largest products track the T-bill end of the curve, with yields clustered around 3.2–3.6%. Only 0.006% of supply turned over in August, while holder concentration remains high across many of the largest funds, consistent with institutional rather than broad retail use. With limited long-duration exposure and very little secondary trading, the segment offers little insight into broader macro views on rates.

Commodities

Commodities show a different pattern between accumulation and trading exposure. The growth in tokenized gold ounces tracks the accumulation in the broader market, with $5.4B worth of gold now tokenized, while oil is mostly traded through perpetuals. On the perpetuals side, gold points to steady accumulation of directional price exposure, while oil is more actively traded around price moves and major events. On prediction markets, gold generates the most commodity volume, but oil lists more contracts on the events that move the price. These contracts form a thinner, named-event layer on top of an existing futures market.

Credit

Credit is the most heterogeneous RWA class, reflecting the diversity of the underlying credit market. The $7.8B market spans senior AAA CLO tranches, overcollateralised lending, payment receivables, private loans and reinsurance-linked credit, with yields across the largest products ranging widely. Private credit alone spans roughly 4–8% among the largest products, making the label a poor guide to risk or return. Credit is also the RWA class most used as collateral on decentralized lending protocols, unlike traditional collateral markets where Treasuries and other government-backed securities are more commonly used.

Equities

Equities remain the smallest tokenized RWA class by AUM at $2.8B, but both AUM and holders have grown by more than 2,000% year on year, making them the fastest-growing and most widely held class. They are also the most actively traded, with $12.6B in spot and $72.4B in perpetuals in August. While offchain listed ETFs now outnumber listed stocks, single names lead the onchain market, giving exposure to a mix of US compute companies, Asian memory and storage names, regional indices and pre-IPO companies, with prediction markets adding a wider menu of event-driven markets around earnings, M&A and more. They also trade when the listed market is closed, so there is still a read on positioning overnight and at the weekend.

1

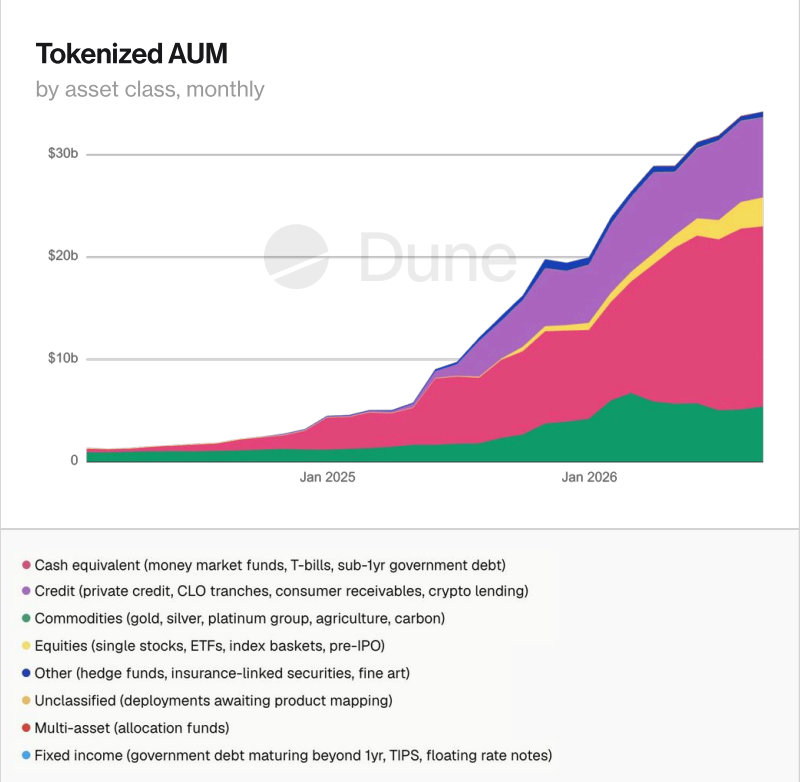

The four classes compared

Tokenized assets have grown rapidly, but size and market activity are moving in opposite directions.

Cash equivalents are the largest class at $17.8B, followed by credit at $7.8B, commodities at $5.5B and equities at $2.8B.

The four classes are $33.9B of the $34.5B market. The remainder is other assets at $535.4M, chiefly reinsurance and crypto basis funds, and fixed income at $16.3M.

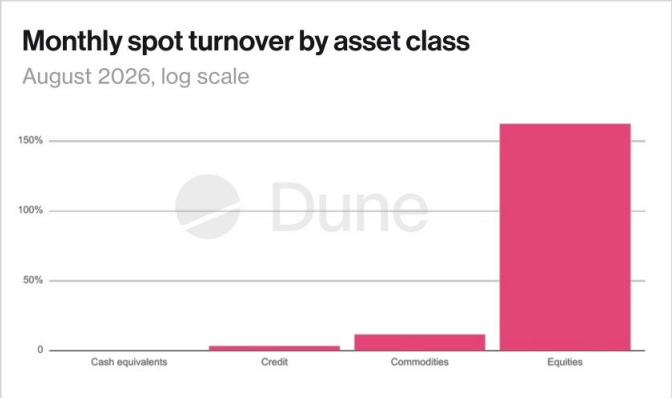

Equities have separated from the rest of the market on growth. Supply increased **2,393%** over the past year, compared with 111–138% for the other three major classes. Despite representing only 8% of supply, equities generated **93% of August spot volume on decentralized exchanges.**

DUNE.COM/QUERIES/8586063/12599283

2,393%
Equities supply increase

	CASH EQUIVALENTS	CREDIT	COMMODITIES	EQUITIES
AUM	$17.8B	$7.8B	$5.5B	$2.8B
12-month growth	133%	111%	138%	2,393%
Holders	50,329	148,546	283,730	1,066,710
Holders per $100m	283	1,907	5,121	37,501
August perpetual volume	–	–	$13.3B	$72.4B
Perpetual open interest	–	–	$421M	$1.52B

DUNE.COM/QUERIES/8724397/12749416

The divergence is most visible in turnover. Cash equivalents turned over only **0.006%** of supply in August, compared with **162% for equities.** The equity figure excludes QQQB, which traded $7.9B on $31.2M of supply during a Binance fee promotion; including it, equity turnover reads 443%.

0.006%

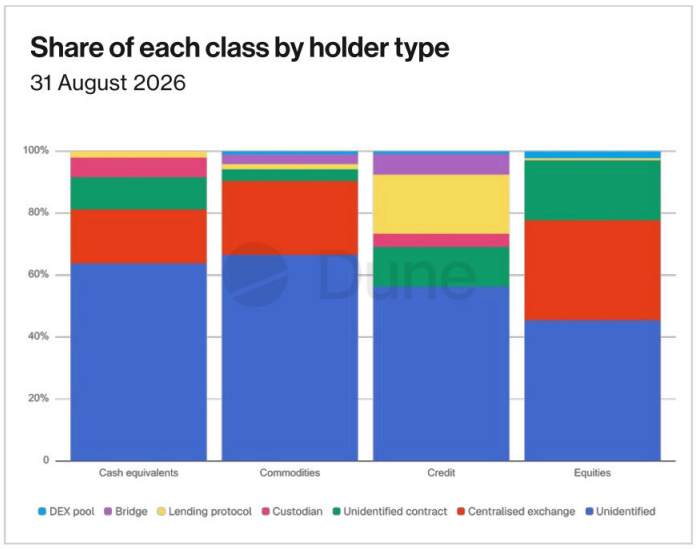

Of cash-equivalent turnover in August

Market activity reflects asset function

Cash equivalents have a high custodian concentration and almost no secondary trading, but this appears to reflect their function rather than weak adoption. For a money-market fund, turnover is more likely to reflect redemptions than successful distribution. The available data therefore point to a market designed primarily for **holding and transferring yield-bearing cash exposure,** rather than trading it.

Credit shows a different structure. **About $1.5B, or 19.1% of its observed holdings, sits in lending protocols,** compared with 2% or less for every other major class.

Equities combine the broadest holder base with the highest secondary activity, reflecting the availability of exchange-based trading and perpetual markets.

SPOTLIGHT

Prediction markets broaden synthetic exposure

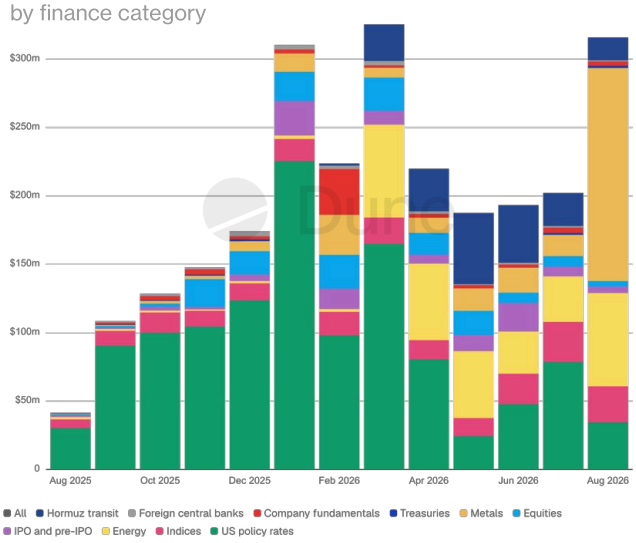

Gold and equity indices are available onchain as both tokenized assets and perpetuals. Prediction markets offer a different type of synthetic exposure: rather than betting on an asset's price, traders can take positions on the **specific events that move** it by trading binary outcomes.

The mix has changed sharply over the past year. Metals grew from just $354,000 in August 2025 to $155M in August 2026, more than five times their previous peak. US policy-rate markets, by contrast, fell 85% from their January high of $225M, while equities fell 83% from February.

Gold alone accounted for $112M of volume in August, mostly through Kalshi's 15-minute direction series. Silver added $40M and copper $2M, accounting for nearly all remaining metals activity.

Energy contracts on Polymarket and Kalshi traded **$68.1M of volume** in August. Geopolitical oil-related markets traded another **$20.2M across 492 markets** on Strait of Hormuz transit, and $109M across the whole Iran complex. Transit through the strait was the variable setting the oil price for most of 2026: J.P. Morgan had Brent at or above $100 for most of the second quarter, falling under $70 in mid-June once the strait reopened, and cutting its end-2026 forecast to $78 from $95. That reopening did not hold, and on 17 September the bank withdrew its baseline view for the oil market altogether, six months into a conflict in which every economic threshold it had expected to force a settlement had been crossed without one.

Policy-rate markets traded **$34.5M,** almost all of it on the Fed, split $24M on Polymarket and $10.6M on Kalshi. Every other central bank together drew under $0.5M, while the two rates perpetuals that exist, a 10-year Treasury yield contract and a long-duration Treasury bond contract, traded $7.8M between them over the same month.

DUNE.COM/QUERIES/8833436/12874958

Equity markets traded $165M over the year, and two market types account for most of it. At $98M, market-cap rankings were the largest, with 297 markets asking which company would be the world's largest by market cap at a given month end. Single-name price ladders and daily direction generated another $65M, spread across 20,831 markets. Separately, markets on company earnings and revenue traded $12M.

Prediction markets also extend into exposures that are difficult to access elsewhere. IPO and pre-IPO markets traded $61M, led by SpaceX before its June listing, followed by Anthropic and OpenAI.

These markets remain small beside the $85.7B of RWA perpetual volume in August. But they expand the range of synthetic exposure beyond asset prices, allowing traders to isolate specific events and variables that drive markets.

2

Cash equivalents

Tokenized cash equivalents market remains concentrated in short-duration government exposure

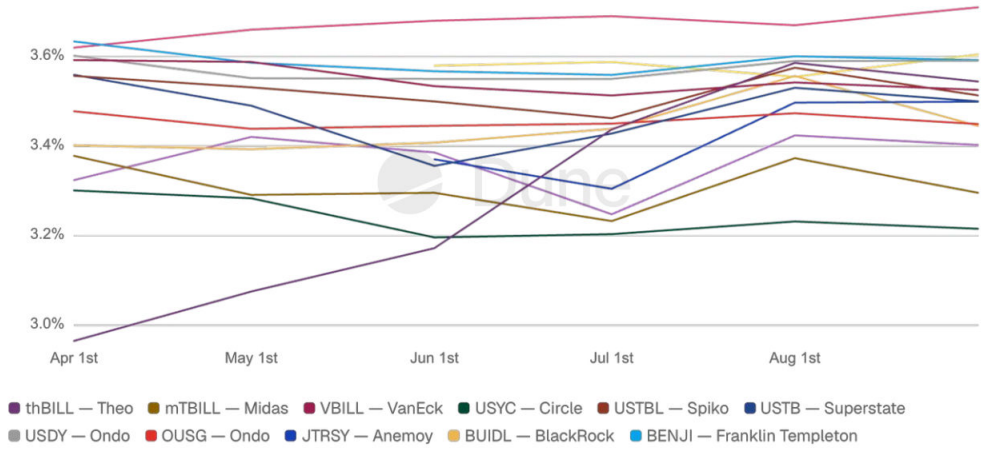

Cash equivalents grew **133%** over the past year and now represent 52% of tokenized RWA supply. Eleven products account for $11.6B and generate realised yields between **3.22% and 3.59%,** a spread of only 37bp.

The narrow range reflects the same underlying asset, the Treasury bill. These yields are 90-day trailing returns, so the comparable bill is the one an investor could have bought when the window opened: 3.71% on a 13-week coupon-equivalent basis on 3 June. **Every fund came in below it,** and the same held at every point since April. Fees account for most of that: Circle, for example, charges a **10% performance fee** on USYC, which takes a 3.58% gross yield to 3.22% net.

133%

Cash equivalents growth in past year

Realised yield, tokenized USD government money funds

DUNE.COM/QUERIES/8745586/12772047

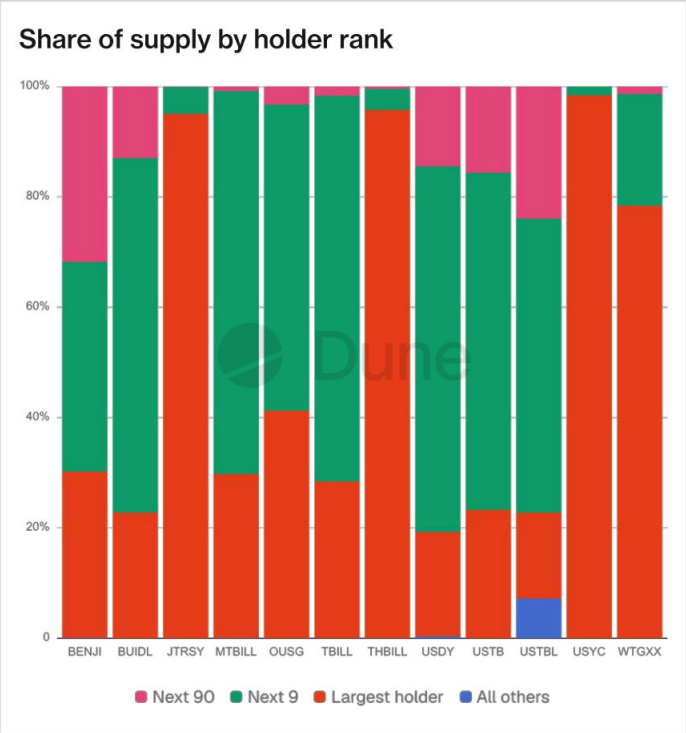

By comparison, tokenized credit spans **1,052bp,** from 3.32% to 13.84%. The much wider dispersion reflects different underlying risks rather than simply different implementations of the same asset.

Higher yields generally imply different risk

Products that sit above the money-fund range generally achieve the additional yield by taking additional risk.

Spiko's SAFO and eurSAFO use fully collateralised total-return swaps with G-SIB counterparties rather than holding Treasury bills directly. The additional yield reflects the cost of moving that exposure onto the bank's balance sheet: the fund receives the bank's obligation, backed by collateral, rather than holding the underlying government securities itself. CUMIU permits regional bank time deposits and Asian money-market instruments, introducing bank credit exposure.

These products should therefore not be viewed as higher-yielding versions of the same Treasury exposure. The additional return compensates for additional counterparty or credit risk.

DUNE.COM/QUERIES/8829944/12862029

Holder counts vary widely, but reveal little about distribution

Holder counts vary widely across products, even if yields are similar. BUIDL holds **$2.82B across 93 addresses,** while USYC holds $2.76B across 28. At the other end, mTBILL has $72M across 5,102 addresses and USDY $2.17B across 19,289.

Those counts do not show how the capital is spread. In four products one address holds most of the fund: 98% of USYC, 96% of thBILL, 95% of JTRSY and 78% of WTGXX. These are effectively single-mandate vehicles.

The same pattern appears in products that look retail by headcount. mTBILL has 5,102 holders, yet its top ten addresses hold 99.1% of supply. BUIDL and USDY are the least concentrated in the group: their largest wallets hold 23% and 19%, while the top ten account for about two-thirds. One caveat: an address is not necessarily an investor. A custodian can stand in front of many holders, while one institution can split its position across several wallets.

Access and mandate help explain the difference. Midas sells mTBILL to European retail with no minimum; BUIDL is limited to qualified purchasers with a $5M ticket. Many of these products have tight access because they are cash-management tools for institutions, protocol treasuries and other large balance sheets. KYC, permissioned access and large tickets are part of the design, unlike tokenized equities or gold, which can accommodate many smaller positions. Holder counts therefore tell us more about who can buy and how a position is held onchain than about how widely the capital is distributed.

Why demand for tokenized Treasuries is short-dated

At 31 August the Treasury curve, on a constant-maturity basis, ran 3.91% at three months, 4.75% at ten years and **5.25% at thirty years.** The long bond was paying more than any of the three largest tokenized credit products, at lower credit risk.

Analysis and strategy concentrate at the long end of the curve, where the link to the policy rate is less direct. Longer bonds have to price future rates, inflation and a term premium. Goldman Sachs put real yields at almost 2.5% in the 10-year and around 3% in the 20-year in August, describing both as historically elevated against the TIPS market's record and as a reason to own duration.

Onchain, the long end of the curve exists. WisdomTree offers several long-duration Treasury products, alongside products from Etherfuse and others. But these products have attracted very little capital compared with T-bill and money-market products, which account for more than 95% of tokenized Treasury exposure.

Corporate treasuries, protocol treasuries and stablecoin reserves generally want a stable NAV, short duration and quick redemption. Money-market funds and T-bill wrappers fit that use case. Most of the Treasury curve does not.

INDUSTRY VIEWS

> Cash drag is a legacy-market problem. By enabling 24/7 trading and instant settlement for tokenised money market fund shares, WisdomTree is giving institutions a more efficient route into on-chain Treasury yield: when they need it, not when legacy settlement cycles allow it.
>
> **— Dovile Silenskyte, Director, Digital Assets Research, WisdomTree**

WisdomTree®

> The industry has moved beyond proof-of-concept and into the early stages of scaled adoption.
>
> **— Angus Fletcher, Head of Digital Assets, State Street**

STATE STREET

Step one was getting a great treasury product onchain managed by a world-class asset manager, Janus Henderson. Step two was giving that product better liquidity and utility than traditional MMFs allow. This includes a $1B instant redemption facility and composability across vaults and DeFi protocols. JTRSY's liquidity and reliable exit paths bring it closer to behaving like cash in practice, while expanding its use across lending, stablecoin infrastructure and other DeFi markets.

— Bhaji Illuminati, CEO, Centrifuge

Centrifuge

The beauty of tokenized money market funds is that the holder keeps the yield. By canonically tokenizing a money market fund, incremental utility is unlocked versus its untokenized peers. For example, intraday yield is paid until the moment of transfer; this results in real economic value for holders. Tokenization of course unlocks 24/7 transfers and this utility makes tokenized money market funds an ideal collateral asset. Think about it: faster collateral settlement can actually lower collateral requirements while simultaneously lowering risk.

— Chris Perkins, Head of Franklin Crypto, Franklin Templeton

FRANKLIN TEMPLETON

As tokenized cash and short-term government debt markets evolve, differentiation will increasingly come from how easily assets can move between traditional and digital markets and how broadly they can be used across reserve management, treasury and collateral. As new rules under the GENIUS Act take effect, greater transparency and reporting will make data and analytics even more important for understanding adoption, liquidity and how these markets are being used.

③

Commodities

Tokenized commodities are, for now, essentially a gold market

The class reached **$5.5B,** up 138% over the past year. Metals account for 99.9% of supply, with gold alone representing 97% of the class.

Two products dominate: Tether's XAUt at **$3.2B** and Paxos's PAXG at **$1.9B.** Together, they account for **92%** of tokenized commodity supply and 95% of tokenized gold.

DUNE.COM/QUERIES/8665755/12862063

Tokenized gold stays close to the physical asset

Matrixdock's XAUm is a distant third at $49.1M. All three give holders a claim on allocated physical gold, but the route to redemption differs in how much metal must be assembled, where it is delivered and who may ask.

This constraint comes directly from the physical gold market these tokens represent. A London Good Delivery bar is 350–430 fine ounces and cannot be divided, so issuers set redemption at 430 ounces — 430 tokens, at one token per ounce — to be sure one bar is covered. XAUt redeems in full bars in Switzerland, at 25 basis points plus delivery. PAXG uses the same 430-token threshold for a Good Delivery bar into London vaults. XAUm sets a lower floor at one kilogram, about $143,000 at August's gold price, collected in Singapore or Hong Kong.

In practice, owning less than a bar's worth of tokens does not mean you can take delivery of the underlying gold. SPDR Gold Shares works the same way at a different scale: it holds allocated gold, but only authorised participants can redeem, and only in 100,000-share baskets. PAXG is the exception, offering fractional redemption through partnered gold retailers.

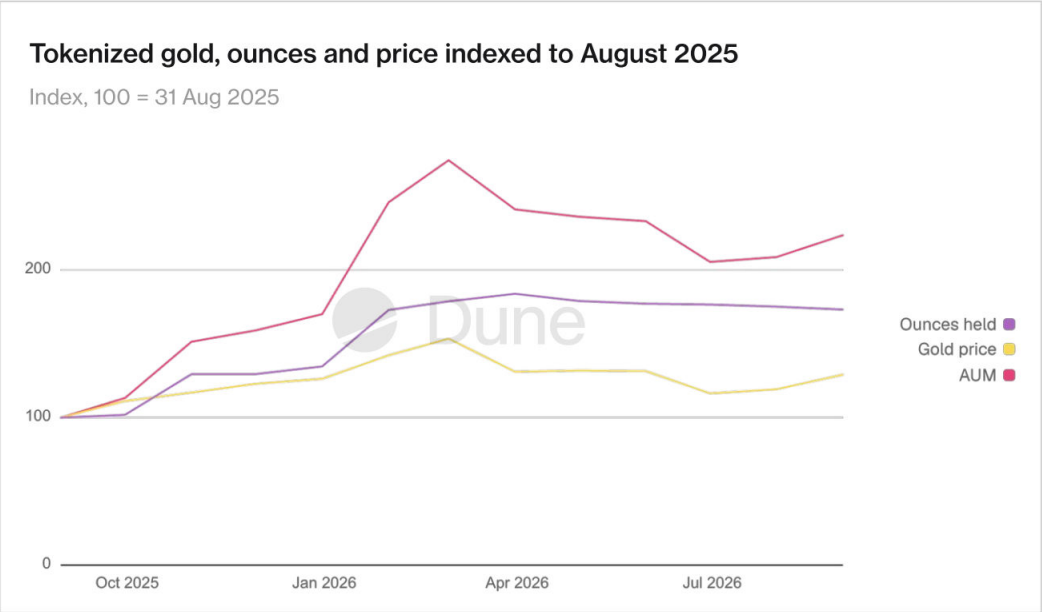

97%

Gold share of tokenized commodities

Tokenized gold is growing through both price and demand

Across the redeemable one-ounce products, XAUt, PAXG, XAUm and DGLD, AUM increased 124% over the past year, while the number of ounces held rose 73% and the gold price increased 29%. The gap suggests that most of the growth came from additional gold being accumulated rather than from price appreciation alone.

DUNE.COM/QUERIES/8724807/12862068

That pattern extends well beyond tokenized markets. Goldman Sachs forecasts gold at $4,900 per troy ounce by the end of 2026 and expects central banks to buy an average of 50 tonnes a month, versus 17 tonnes before 2022. The ECB's reserve data put gold at 27% of official reserve assets at end-2025 and US Treasuries at 22%.

Tokenized gold's onchain presence remains small by comparison, at roughly 36 tonnes, versus more than 36,000 tonnes held by central banks globally. Gold ETFs are another order of magnitude larger, with 4,189 tonnes and $615B in holdings at the same date, according to the World Gold Council.

Tokenized gold represents 0.86% of the gold held in ETFs, but traded $604M of DEX spot volume in August against roughly $9T across the global gold market, or just 0.007%. Tokenized gold has a much larger presence as a holding than as a traded asset.

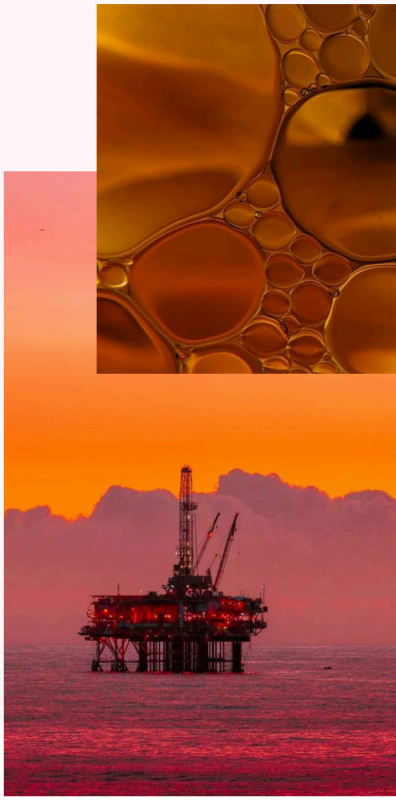

COPYRIGHT © 2026 DUNE

Onchain, perpetuals are a fringe market for gold and the whole market for oil

Gold perpetual open interest on Hyperliquid grew from $2.5M at launch in December to $165M in August, a 66-fold increase that is still only about 3% of tokenized gold supply. Oil and gas is the reverse: **97.6% of the onchain exposure is in perpetuals,** with only $4.3M in tokenized spot.

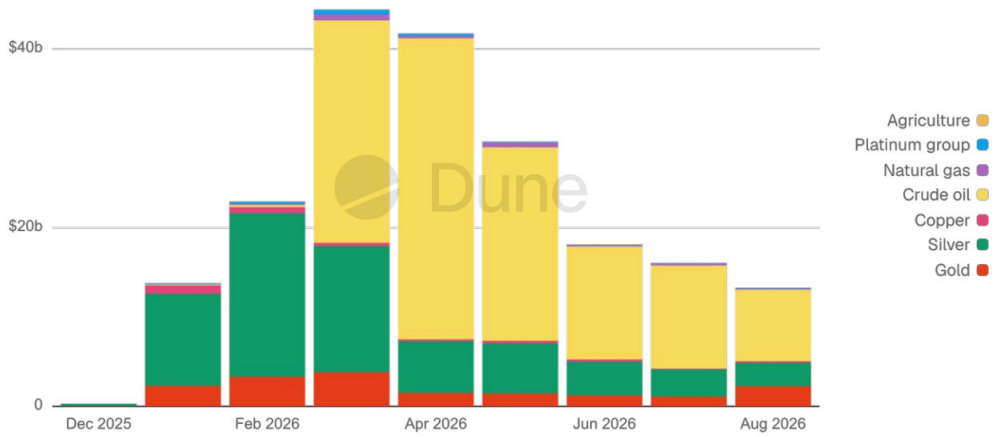

97.6%

of onchain oil and gas exposure is in perpetuals.

Commodity perpetual volume

by underlying, monthly

DUNE.COM/QUERIES/8728876/12754160

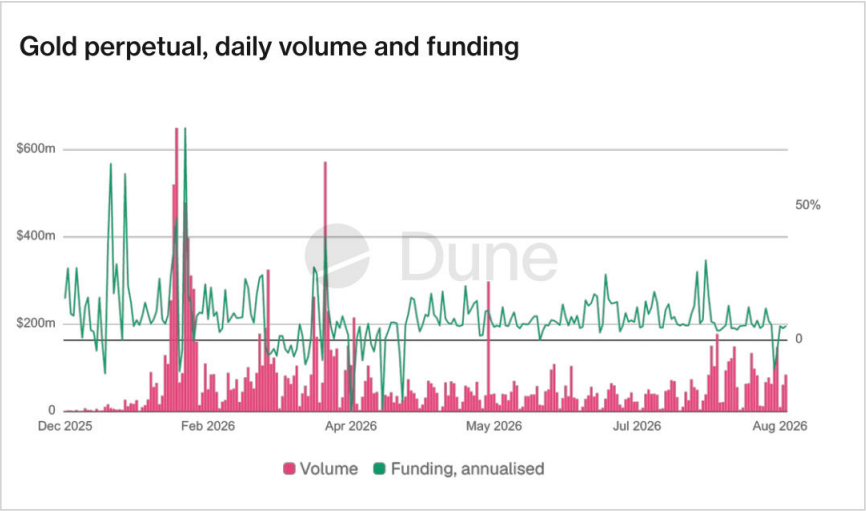

In August crude was **60.5%** of commodity perpetual volume, silver 19.6% and gold 17.1%. Crude turned over **46 times** its open interest that month, gold 14 times, silver 41 times.

Reading funding rates, volume and open interest together reveals more about how these two commodity perpetuals are actually used.

On Trade[XYZ], the builder DEX carrying 96% of gold volume across six gold markets, funding was positive on 88% of days, averaging 13.5% annualised in December and 6.4% in August. It remained stable across activity levels: median funding was around 8.5% annualised across the quiet, middle and busiest thirds of the volume distribution, as daily volume ranged from $11.5M to $141M.

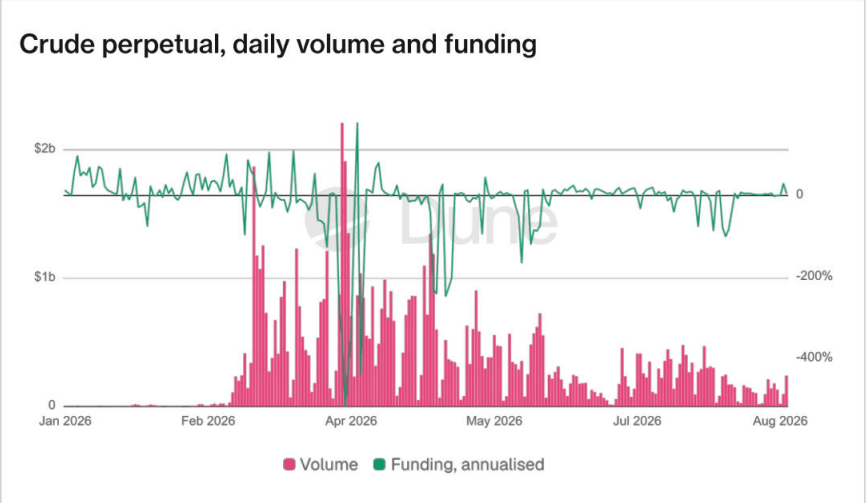

Crude shows a different pattern. Funding averaged −12.4% from December 2025 to August 2026 and was negative on 40% of days. Its median rate fell from 9.7% on quiet days to 5.1% in the middle and −9.4% on the busiest days, when the book turned net short. The average on those busiest days was even lower at −58%.

The open-interest pattern adds the last piece. Gold increased 66-fold, but only 55% of positions opened during spikes remained five days later, while positions that predated the spikes remained at 105% of their pre-spike level. Gold's growth therefore comes from a persistent core of positions, with the additional activity around volume spikes fading quickly. Crude is also building open interest, but more of that growth comes on the busiest days, when funding has already turned negative.

DUNE.COM/QUERIES/8826065/12857645

The growth therefore looks different in the two markets. Gold's persistent open interest, relatively stable positive funding and fading bursts of new positions are consistent with a long position that is being carried, with trading activity layered around it.

DUNE.COM/QUERIES/8826066/12857646

Crude's higher turnover, negative funding on the busiest days and growth in open interest as activity rises are consistent with a more actively managed position, potentially reflecting hedging around oil price moves. The onchain data cannot establish where that hedge lives, whether in futures, physical oil or somewhere else.

INDUSTRY VIEWS

Gold has earned trust as a safe asset over thousands of years but it has never had a tech upgrade until XAUt. Previously gold was expensive to store and transfer and increasingly inaccessible as rising prices increased the cost to buy small amounts. XAUt has changed that, with billions of dollars worth transferred quickly and securely every month for an average cost of just 3 cents per ounce. The demand for this is clear, with XAUt becoming the largest single Real World Asset, meaning that Tether offers both the largest stablecoin and largest RWA.

SPOTLIGHT

Compute is becoming a commodity

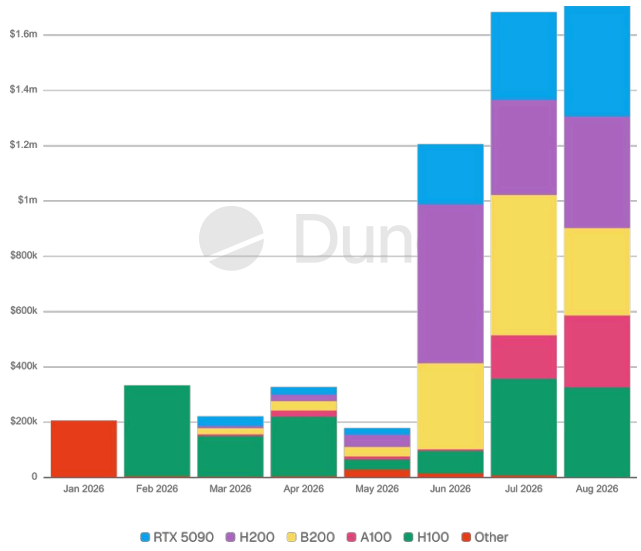

The AI boom has turned compute into a scarce and increasingly valuable resource. As demand for GPUs grows, markets are trying to price, trade and finance it like a commodity.

NVIDIA and six asset managers are targeting more than **$500B of capital** for AI-compute infrastructure. The CFTC has sought input on compute derivatives, and CME is preparing to list H100 and B200 rental futures on NYMEX. Each contract represents one month of rental for a single GPU and settles against the Silicon Data index. Larry Fink has described the emerging market as a futures market for computing power.

Prediction markets are already pricing GPU rental rates. Kalshi's compute rental markets grew from **138 markets and $0.18M of volume in March** to 1,208 markets and $1.46M in August. Polymarket has offered them since February, initially against the Silicon Data H100 index and, since late May, against Ornn's H100, H200, A100 and B200 indices; its 144 markets traded $0.25M in August.

Combined monthly volume rose from $0.22M to $1.71M, a 670% increase, while activity expanded across chip models and generations. The result increasingly resembles a commodity complex rather than a single contract.

Compute rental markets, monthly volume by GPU model

DUNE.COM/QUERIES/8726072/12751243

The challenge, as BCG notes, is standardisation. H100 benchmarks such as Ornn and Silicon Data use different methods to normalise hardware, so the same GPU can command materially different prices across indices. BCG estimates the compute market at $360B in 2025, rising to roughly $2.3T by 2030, and says a liquid market could unlock as much as $140B a year of value now trapped in opaque bilateral deals.

Prediction markets' $1.71M of August volume is still small beside the $13.3B traded in commodity perpetuals. But the building blocks are emerging: price benchmarks, standardised contracts, derivatives and a regulated venue.

670%

Combined prediction markets monthly volume increase

④

Credit

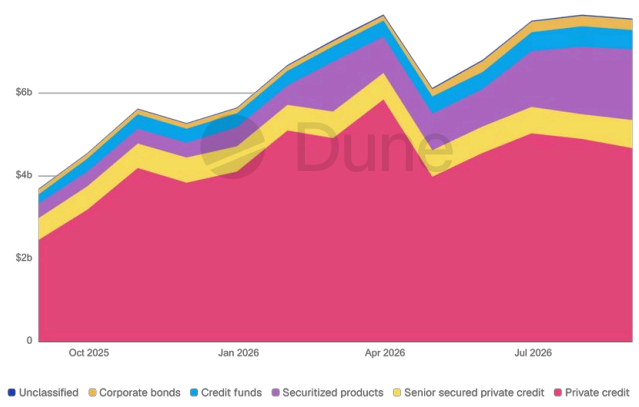

Credit is the most heterogeneous asset class, and the one most widely used as lending collateral

Tokenized credit reached $7.8B, up 111% over the past year. Private-credit lines account for 75% of the class, with the rest in securitized products, mostly CLOs, and a small share of corporate bonds. Against the $1.4T in US private-credit funds and BDCs recorded by the Federal Reserve at end-2025, tokenized private credit amounts to roughly 0.4%. But considering 42% of those lines involves digital-asset collateral or crypto counterparties, the comparable share is closer to 0.2%.

This breadth reflects the diversification of the broader private credit market, which Cleary Gottlieb notes has expanded into consumer receivables, real estate and other specialised forms of lending.

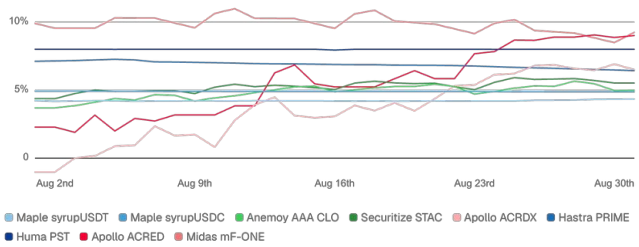

Securitized products gained the most share within the class, rising from 9.5% to 21.9% over the year. Supply grew from $352M to $1.71B as JAAA and STAC scaled. Private credit, by contrast, peaked at $5.85B in March and has since fallen to $4.67B. Most of the April decline came from Maple, the dominant issuer, whose pools halved as more than $800M was redeemed over 72 hours following the KelpDAO bridge exploit, alongside broader deleveraging of looped positions.

Tokenized credit supply by asset type, monthly

DUNE.COM/QUERIES/8826589/12858245

Credit realised yield, August 2026

DUNE.COM/QUERIES/8840907/12874148

The dispersion in yields is correspondingly large, with private credit alone ranging from 4% to 8%. That reflects the fact that these products generate returns from very different underlying businesses, with very different risk profiles.

At the safer end are AAA CLOs and overcollateralised lending. Senior CLO tranches are paid first and absorb losses only after junior tranches, while overcollateralised loans have more collateral than outstanding debt. Hastra's PRIME earns more by financing home-equity lines, where borrowers carry greater credit risk despite the property backing. Huma's PST sits higher again, financing payment-settlement receivables that typically turn over within one to seven days. The book rolls quickly, keeping duration short, but repayment remains the key risk.

At the top end are products taking more specialised credit risk: Re Protocol's reinsurance-linked paper (13.84%), Plume Arc's Brazilian receivables vault (12.27%) and Midas's feeder into a credit fund (11.42%).

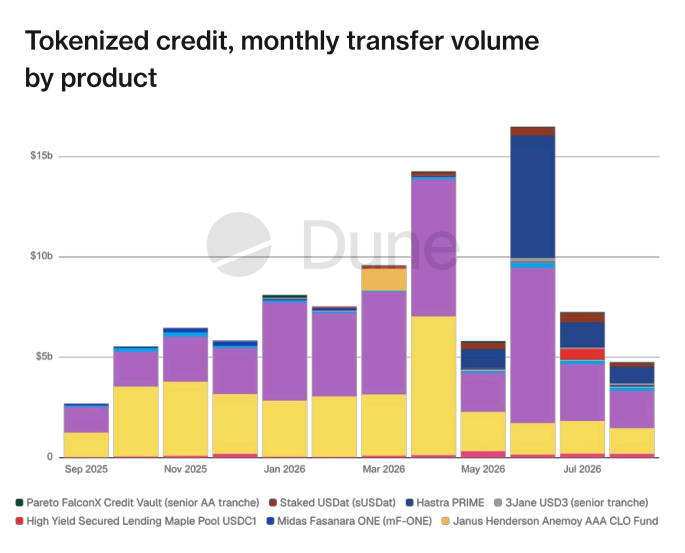

This dispersion, driven by underlying risk rather than the credit subclass itself, mirrors the broader market. Goldman Sachs identifies dispersion in outcomes as a key feature of private credit and argues that credit selection is becoming increasingly important as differences between managers and strategies widen.

Crypto lending is a substantial part of tokenized credit

At 31 August, **$2.45B, or 32% of tokenized credit,** involved digital-asset counterparties or collateral.

Maple accounts for $2.19B, while FalconX and Valos add $263M. Much of this exposure resembles repo or secured financing more closely than conventional private credit: capital is lent against digital assets or to established crypto businesses rather than directly financing households or companies in the real economy.

The other 68% is more closely tied to traditional credit markets, spanning AAA CLOs, home-equity lines, consumer receivables, payment settlement and middle-market lending.

DUNE.COM/QUERIES/8840814/12873990

32%

Of tokenized credit involved digital asset counterparties or collateral

Access terms influence secondary activity

Four products available without allowlists or onboarding — Maple's syrupUSDC and syrupUSDT, Hastra's PRIME and Huma's PST — account for **$2.68B** and generate most of the secondary activity, including holder-to-holder transfers and use as collateral in lending protocols.

By contrast, roughly **$3B** across products requiring KYC, issuer approval or platform-managed positions recorded little to no holder-to-holder transfer activity over the 90-day period.

Accessibility helps explain why tokenized credit can be substantial in size while remaining thinly traded. This is consistent with the broader private-credit market, which the Federal Reserve describes as a market where loans are typically held to maturity and valued periodically rather than traded continuously.

SPOTLIGHT

AAA CLOs are emerging as a major tokenized credit exposure

Two tokenized AAA CLO funds hold $1.27B, equivalent to about 2.5% of the $50B US CLO ETF market that BofA estimated in early July. The tokenized market is still small relative to its traditional counterpart, but AAA CLOs are also the fastest-growing segment of tokenized credit, with their share more than doubling over the past year.

The largest is Centrifuge's JAAA fund managed by Janus Anderson at $909.7M. Its traditional counterpart, JAAA, passed $30B in assets in August. Centrifuge gives non-US professional investors access to the same AAA CLO strategy through a BVI fund that holds the CLO tranches directly, rather than JAAA shares. It therefore has different access and redemption terms from the ETF, including KYC onboarding and offchain redemptions. Securitize's STAC, managed with BNY as custodian, holds another $355.8M. No other dedicated AAA CLO fund exceeds $20M.

AAA CLOs sit at the low end of the credit risk spectrum. JAAA yields 4.13% and STAC 4.20%, among the lowest yields in the class, reflecting the seniority and credit quality of the underlying tranches: no AAA CLO tranche has defaulted in more than 30 years. That combination of credit quality and yield has made the funds useful as reserve assets.

Sky seeded the tokenized fund (JAAA) with up to $1B through Grove at launch in 2025, holding it alongside tokenized Treasuries from Janus Henderson and BlackRock. Ethena added JAAA in June 2026 as its first non-Treasury RWA, funding $200M through Centrifuge on Solana and committing a further $250M to STAC. Outside the reserve use case, Resolv has capacity for up to $100M of JAAA as leveraged collateral on Aave Horizon.

JAAA + STAC

INDUSTRY VIEWS

Tokenized private credit preserves the same underlying credit risk and economic exposure as traditional private credit, but it has the potential to improve market accessibility and operational efficiency. Tokenization can significantly reduce minimum investment thresholds and facilitate transactions through blockchain-based infrastructure and smart contracts, broadening participation beyond the traditional institutional investor base. However, tokenization alone does not create secondary market liquidity, nor does it inherently enhance transparency. These outcomes depend on the depth of market participation and on whether origination, underwriting, reporting, and ongoing monitoring processes evolve alongside the technology.

— Cristiano Ventricelli, Vice President, Digital Assets, Moody's Ratings

MOODY'S

By bringing fixed income onchain through a purpose-built, natively digital strategy, we are extending Wellington's investment capabilities to a new generation of investors. Rather than simply replicating an existing tradfi approach, mWIN is specifically designed to meet the needs of onchain investors by targeting attractive yield, maintaining liquidity, and managing downside risk. Built on Wellington's decade-plus Income Opportunities strategy, mWIN applies a diversified public credit approach with disciplined controls around interest-rate and credit risk, supported by deep fundamental credit research. This has enabled mWIN to service clients looking for a high quality, yield producing DeFi collateral asset to power their investment strategies.

— Geoff Austein-Miller, Investment Director, Wellington Management

WELLINGTON MANAGEMENT®

Modern asset allocation is built around combining distinct sources of risk and return across the yield curve. Until now, onchain fixed income has been dominated by short-duration Treasury exposure. JAAA expands that opportunity set by bringing AAA CLO exposure onchain: a strategy that sits at the senior end of the credit spectrum, offers additional spread over government bonds, and gives investors exposure to diversified corporate credit risk.

Equities

Equities are the smallest tokenized asset class among the four, but the fastest growing and most actively traded onchain.

Equities are the smallest of the four classes at **$2.8B,** but the most widely held, with over **1M holders.** They are also the fastest growing on both measures: supply is up **2,393%** over the past year and holders 2,454%. Equity perpetuals add **$1.52B of open interest,** 78% of the RWA total.

Equities are also the largest class by DEX volume, both spot and perpetuals. August tokenized spot volume reached **$12.6B,** or 93% of all RWA spot volume, while equity perpetuals generated **$72.4B,** or 84% of RWA perpetual volume.

One token accounts for a large part of the August DEX spot figure. QQQB, a bStocks token tracking Invesco's QQQ, generated **$7.9B** of August volume against just $31.2M of supply.

Binance listed it on 30 June with zero maker fees and, from 23 July, counted traded value at three times its face value toward VIP tiers. Even excluding this outlier, equities still account for **83%** of remaining onchain DEX spot volume.

1M+

Equity holders

The market is diversifying quickly. Tokenized spot went from seven underlyings above $1M in June 2025 to 247 by August 2026, while perpetual markets rose from one to 58. Spot supply has also become much less concentrated: the top five products now account for 21% of tokenized equity supply, versus 82% previously. Perpetuals remain more concentrated at 49%.

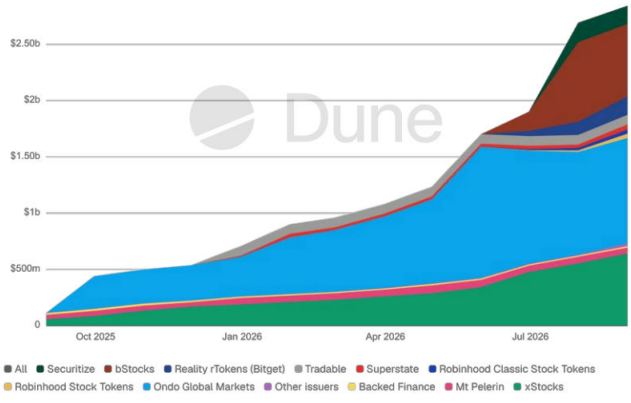

Eleven issuers now hold more than $10M each, led by Ondo Stocks at $936M and Binance's bStocks at $645M, followed by xStocks, Securitize, Bitget, Robinhood and Coinbase. These issuers cover dozens or hundreds of individual stocks, indices and ETFs, compared with the handful of products typically offered in tokenized cash equivalents or credit.

Tokenized spot against perpetuals, August 2026

AUGUST 2026	TOKENIZED SPOT	PERPETUALS
Size	$2.8B AUM	$1.52B OI
Volume	$12.6B	$72.4B
Share of RWA volume	93% SPOT	84% PERP
Largest IT segment	CRYPTO LINKED $340M	MEMORY/STORAGE $524M
US share	91%	73%
Asia share	3%	24%
Underlyings >$1m	247	58
Top-five concentration	21%	49%

DUNE.COM/QUERIES/8827113/12858819

Tokenized equity supply by issuer, monthly

DUNE.COM/QUERIES/8827530/12859315

Onchain equity exposure is shifting toward single names

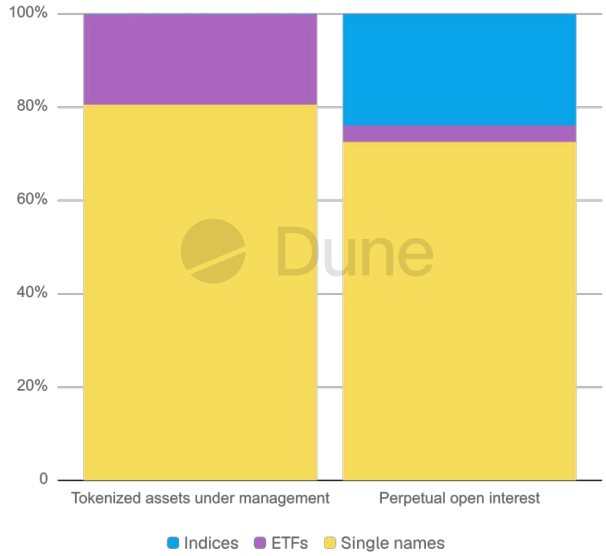

Single names account for 81% of tokenized spot supply and 73% of perpetual open interest. The remainder inverts: ETFs are 19% of spot and 4% of perpetuals, indices 0.1% of spot and 24% of perpetuals.

Fund supply tripled since September 2025, from $186M to $552M, but single-name supply increased 9x, from $253M to $2.28B. The fund share of tokenized spot therefore declined from 42% to 19%. This is the opposite direction from the conventional market, where the number of listed funds continues to expand: Goldman Sachs expects more than 6,000 US-listed ETFs by the end of 2026, more than the number of single stocks in the US market.

Tokenized spot typically holds an underlying ETF, including SPY, QQQ, iShares Core S&P 500 and Vanguard Growth, while perpetuals can reference the ETF or the index itself, with different fee and tracking implications. Venue-built indices add another variation, such as XYZ100, which tracks 100 large non-financial US listings. Perpetuals also cover indices with no tokenized spot equivalent, including the Nikkei 225, NIFTY 50, KOSPI 200, Ibovespa and VIX.

Equity exposure by wrapper

Tokenized AUM against perpetual open interest

DUNE.COM/QUERIES/8759556/12787295

AI exposure is increasingly expressed through perpetuals

The AI trade has moved beyond the companies building AI products to the infrastructure needed to build them. J.P. Morgan described the shift in June, pointing to GPUs, memory, networking equipment, power generation, grid infrastructure, cooling and data-centre capacity as the scarce inputs attracting capital.

Onchain, that shift is concentrated in a narrower part of the value chain, with perpetuals carrying much more of the exposure than spot markets.

Equity IT segment

Tokenized AUM against perpetual open interest

DUNE.COM/QUERIES/8827678/12859517

Memory and storage account for $524M of perpetual open interest, compared with $149M for compute silicon and just $11M for model labs. Spot exposure is more balanced: compute silicon accounts for $271M, led by NVIDIA, Marvell and TSMC, while memory accounts for $249M, led by Micron and SanDisk. The largest spot segment at $340M remains crypto-linked equities including Circle, Strategy, Coinbase and Robinhood.

The difference is even more visible in trading. Memory generated **$34B of August perpetual volume,** or 47% of the equity perpetual market, led by SK Hynix, SanDisk and Micron. On the tokenized side, Nvidia traded $897M, more than two-thirds of AI-related spot volume, across seven products from seven different issuers.

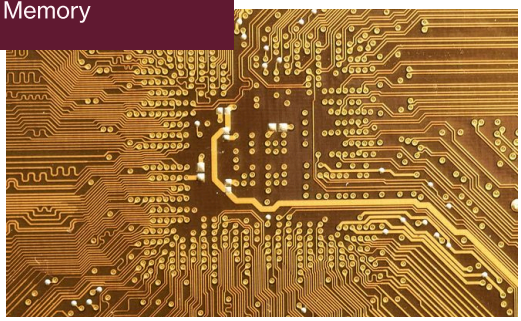

COPYRIGHT © 2026 DUNE

The onchain market has not yet followed the rotation toward hyperscalers that Morgan Stanley highlighted in August. Morgan Stanley called memory stocks overextended after a historic rally, suggesting the better opportunity may shift back to hyperscalers such as Microsoft, Amazon and Alphabet. Yet software and platforms account for only about 5% of IT-related tokenized AUM and perpetual open interest onchain, while memory remains 65% of IT-related perpetual open interest.

A similar pattern applies to power and data-centre infrastructure, which remain much less represented onchain. Morgan Stanley identifies time to power as a key constraint on the buildout, while Citi expects new AI power capacity to rise from 19 GW in 2026 to 45 GW by 2028. UBS extends the buildout into generation, grids and utilities. Utilities account for just $1.2m of tokenized spot supply and $0.5m of perpetual open interest.

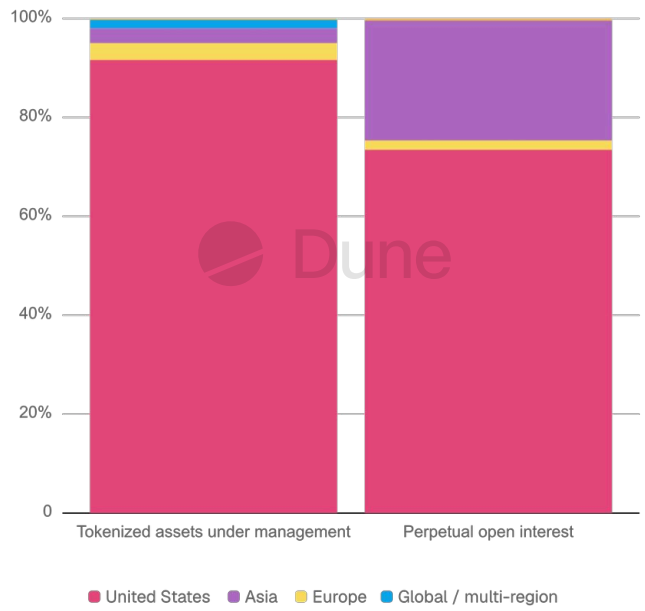

$34B

Equity exposure by geography

Tokenized AUM against perpetual open interest

DUNE.COM/QUERIES/8827686/12859526

Perpetuals have a larger Asian footprint

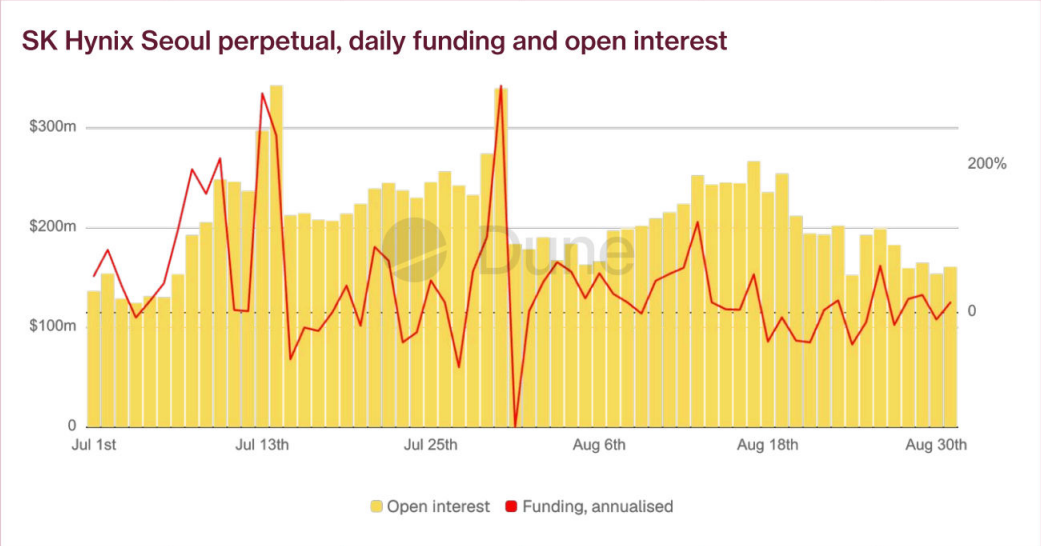

The geographic mix of traded companies broadly follows the sector mix. Tokenized spot is 91% US and just 3% Asia, while perpetuals are 73% US and 24% Asia.

South Korea accounts for $297M of perpetual open interest, concentrated in SK Hynix and Samsung Electronics. China and Hong Kong add another $59m, including ChangXin Memory and Unitree Robotics. The larger Asian share is largely explained by the concentration of memory and semiconductor names in perpetuals.

SPOTLIGHT

SK Hynix and the onchain memory trade

SK Hynix, one of the world's largest memory-chip makers, is a major driver of Korea's equity market: together with Samsung Electronics, it now accounts for over 50% of the KOSPI's market capitalization. Its perpetual market shows how traders could access the stock and position around events while the Korean market was closed.

DUNE.COM/QUERIES/8827927/12859782

308%

SK Hynix peak funding annualised

SK Hynix trades in Korea through its Seoul-listed common share and in the US through a Nasdaq-listed ADS. The US ADS reached a 40% premium to the Seoul share in the week of 10 August and ended August at 34%, which J.P. Morgan, a global coordinator on the ADS offering, attributed to deeper US demand. Arbitrage was constrained by the Korea Securities Depository, which capped conversion of Seoul shares into ADS at 2.5% of shares outstanding; the quota was fully used.

The onchain perpetual provided access to the Seoul line without either constraint. It traded $11.6BN in August, versus $2.6bn for the US ADS contract. Seoul perpetual funding exceeded 100% annualised on eight days in July, peaking at 308% on 30 July, showing how crowded the long side became at the height of the trade. By late August, the funding had turned negative and open interest had fallen from $343m to $161m, marking a clear unwind.

The first signs of the later unwind appeared in July, around the Nasdaq listing. Ahead of the 10 July debut, open interest rose from $130M to $248M and funding reached 209% annualised, as traders paid heavily to stay long through the event. The Seoul perpetual itself moved only 4.3% that day, so the elevated funding and open interest reflected positioning rather than a large price move.

When Seoul reopened on 13 July, SK Hynix fell 15%, but the perpetual saw the opposite response: open interest rose by $60M to $297M and funding reached 297%, as traders added long exposure to the cheaper Seoul line. The Seoul perpetual rallied 16.2% on Tuesday, with open interest peaking at $343M. The following day, funding turned negative and open interest fell by $130m in a single session.

INDUSTRY VIEWS

A share that lives onchain settles in seconds, trades on a Sunday, and can be posted as collateral in a lending market the same day someone buys it. Those are ordinary expectations for a token and brand new ones for an equity. Because it behaves like any other token, the wallets, exchanges, and lending markets that already exist support it on day one.

— Antonio García Martínez, Head of Growth, Base

base

Whether tokenized equities would find real volume was last year's question. Billions of dollars traded onchain in little over a year answered it, and the focus now is scaling to match the ambitions of the largest financial institutions on the planet. Getting there depends on the asset being accessible and dependable at both ends. Open to an investor who has never had a practical route into capital markets from the other side of the world, and reliable enough for developers to build exciting applications that can achieve mass adoption.

— Val Gui, General Manager, xStocks

xStocks

For a global investor, access to U.S. equities has long depended on what a local intermediary chose to offer, and for many that meant a short list of products selected for them. Tokenization changes what can be distributed: exposure to a single company now moves through the same wallets and exchanges as exposure to an index, and the investor decides which they want. Because every position settles onchain, that shift toward individual companies is visible in the data, which is what makes a report like Dune's possible.

— Armand Khatri, Head of Ecosystem, Ondo Finance

Ondo

6

Collateral and liquidity

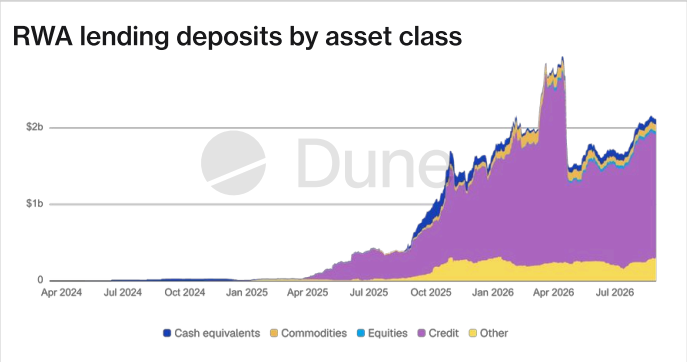

Only 6.7% of tokenized RWA supply is currently active in DeFi

At 31 August, 6.1% of all tokenized supply ($2.11B) sat in lending protocols, spread across seven venues and 113 assets. Another $185m sat in DEX pools.

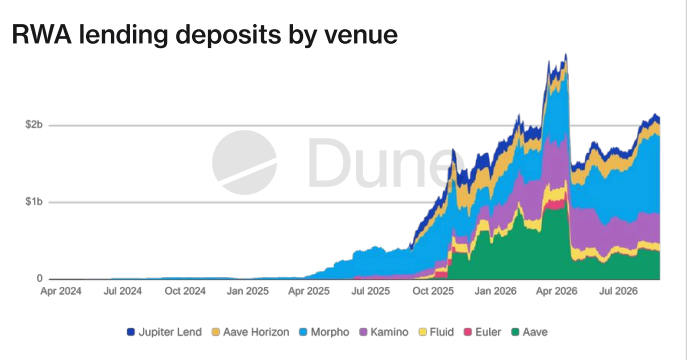

Credit accounts for **$1.61B,** or 76% of lending deposits, equivalent to 21% of tokenized credit. Cash equivalents sit at the opposite end: just $68M, or **0.4%** of their supply, despite accounting for roughly half of the tokenized RWA market.

These figures come from each protocol's own records, which show $1.61B of credit (21% of class supply). Section 1 measures from the token side and finds $1.51B (19.1%).

The lending market is also highly concentrated. Morpho alone holds nearly half of all deposits, at roughly $1B, and together with Kamino and Aave's main market it accounts for 83%. Aave's two deployments add $510M, including $156M on Horizon, its dedicated semi-permissioned market for RWA collateral. Jupiter Lend, Fluid and Euler account for the remaining $202M.

DUNE.COM/QUERIES/8767856/12796407

DUNE.COM/QUERIES/8767858/12796408

Lending deposits by venue and asset class

VENUE	CREDIT	OTHER	COMMODITIES	CASH EQUIV.	EQUITIES	TOTAL
Morpho	$893M	$99m	$11M	$7M	$0.2M	$1.01BN
Kamino	$198M	$171m	$1M	–	$20M	$390M
Aave	$281M	–	$73m	–	–	$354M
Aave Horizon	$61M	$33m	–	$61M	–	$156M
Jupiter Lend	$80M	–	–	–	$20M	$99M
Fluid	$85M	–	$5M	–	–	$90M
Euler	$11M	–	$1M	–	$0.1M	$12M

A current price does not create a liquid market

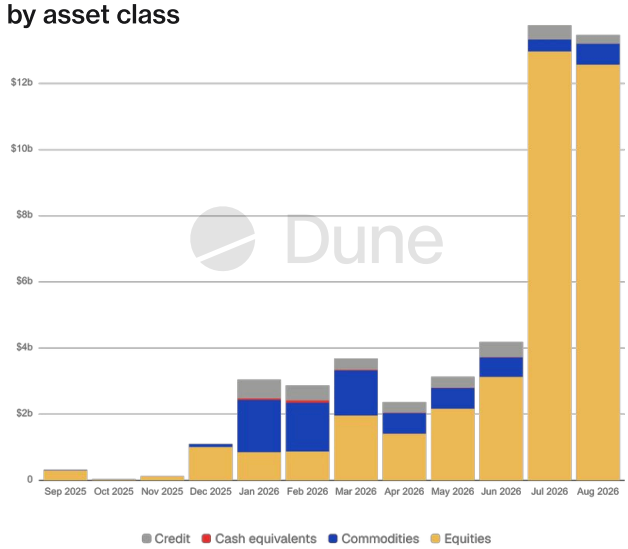

For most RWAs, price discovery still happens offchain. Treasuries follow the bill market and cash rates, credit follows the underlying loans or securities, gold follows the physical market, and tokenized equities follow their listed stocks or ETFs. Onchain markets add basis, leverage and, when cash markets are closed, some incremental price discovery.

That makes a current NAV necessary for lenders to value collateral, market makers to quote prices and buyers to transact, but not sufficient for secondary liquidity.

As an example, **26 cash-equivalent products marked NAV at least weekly through August, but only three traded onchain.** The other 23 held $14.2B, or 86% of the measurable class. Credit is more active, but only 7 of 22 products traded.

The missing ingredient is access. A token can have a reliable price and still be difficult to trade if transfers require KYC, issuer approval or a platform-managed account. Permissionless transfer and an open venue are what turn a marked asset into one that can trade continuously, and into collateral that lending markets will actually take.

Monthly spot DEX volume by asset class

DUNE.COM/QUERIES/8828298/12860232

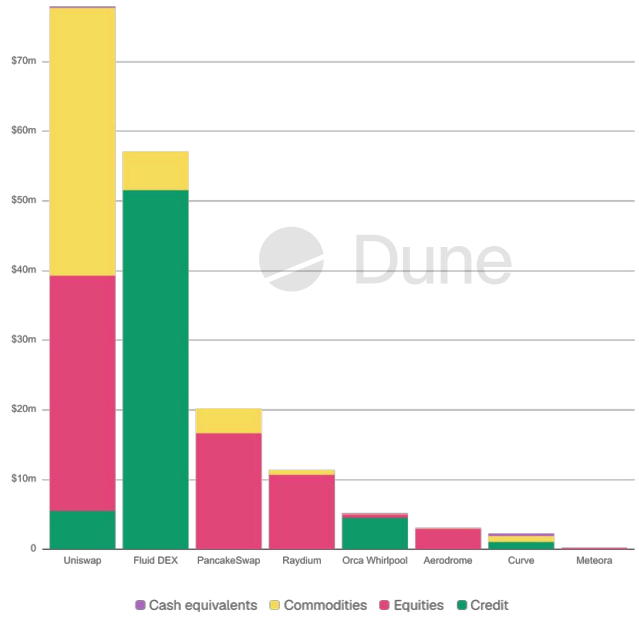

DEX liquidity remains fragmented

Of the $185M of real-world assets in DEX pools, equities hold $69M across **5,484 pools and 1,364 tokens,** compared with $63M of DEX liquidity for credit across just 133 pools. Equity liquidity is spread across Uniswap ($34M across 1,325 pools), PancakeSwap ($17M across 2,283) and Raydium ($11M across 635). Commodities are more concentrated, with $38M of their $49M on Uniswap.

The number of equity pools makes the market look deeper than it is. **The median pool holds just $92,** while 78 pools with more than $100,000 hold $56M, or 81% of all equity liquidity. And even that overstates what a trader can actually access: concentrated-liquidity pools often have much of their capital outside the current trading range.

Credit has a different structure. Of its $63M, $51M sits in a single Fluid venue against Huma's PST, which at that size is more likely lending inventory than a two-sided market.

SPOTLIGHT

Fixed-term lending addresses the collateral problem

One reason RWAs have not been onboarded at scale as collateral in decentralized lending is that many cannot be priced and liquidated continuously. Fund NAVs may update daily or weekly, while permissioned assets cannot necessarily be sold atomically through a DEX. Equities have continuous prices only while their underlying markets are open.

Two emerging lending models take different approaches to this problem.

Jupiter's Offerbook removes price-based liquidation. Loans are fixed until maturity, and if the borrower does not repay, the lender can claim the collateral itself. With no liquidation to cap the downside, collateral risk is priced entirely in the rate. The median crypto collateral pays 25% annualized on loans of about a week, while the most volatile reaches 96%. Tokenized equities range from 11% on MicroStrategy to 22% on SpaceX, while OnRe's tokenized reinsurance is the cheapest collateral in the book at **7.2%** over 22-day terms. Through 31 August, Offerbook had originated **3,202 loans worth $2.77M,** of which RWA collateral accounted for $165,000 across 219 loans, or 6% of the book.

Morpho's Midnight keeps price-based liquidation, but fixes the rate and maturity. The rate is set by trading claims on repayment rather than by a utilisation curve, and those claims can be transferred before maturity. By 31 August, Midnight had 193 markets, although RWA markets had almost no outstanding balances.

That produces a much narrower range of collateral rates: 0.53% on USDC, 3.8% on WETH, 4.0% on cbBTC and 6.0% on its most volatile collateral. Midnight also uses LTV to manage the risk, at 86% on cbBTC versus 98% for stablecoin collateral. Offerbook has no price-based liquidation, so more of the collateral risk has to be reflected in the rate: its collateral rates span roughly 90 percentage points.

Both markets were weeks old at the cutoff. Midnight's collateral set was entirely crypto at 31 August and has since broadened to tokenized equities and other RWAs; these figures describe both protocols as they stood on that date, not as they stand now.

$2.77M

Jupiter Offerbook loan value, through 31 August

"Tokenized RWAs are one of the fastest-growing markets on Morpho, with more than $600 million in deposits out of roughly $1.5 billion in total RWAs on the network. We expect this growth to accelerate as more of the global credit market moves onchain and Morpho Midnight expands. Fixed-term lending is well suited to RWAs because financing can be matched to an asset's maturity and cash flows without relying on continuous pricing or instant liquidation."

— Merlin Egalite, Cofounder, Morpho.

Morpho

Conclusion

Industry coverage of tokenized assets has so far focused on two questions. The first is stock: how much value has been brought onchain. By 31 August, that stock was $34.5B, up more than 140% over the year, still concentrated in cash equivalents. The second is use: whether that stock has a secondary life at all, whether it trades, is posted as collateral or backs liquidity others can trade against. On that measure, the picture is narrower and uneven. Only $2.1B, or 6.1% of supply, sat in lending protocols, three-quarters of it credit, while DEX pools held another $185M, mostly equities.

The perspective this report introduces is whether these onchain markets show the same patterns as the offchain markets they reference, or whether they behave differently. Where they track, they confirm what the underlying market already says. Where they diverge, they can reveal an exposure or signal that the underlying market does not.

On that measure, the next twelve months are more informative than another increment in AUM. Cash will remain a limited signal unless longer-duration products attract capital. Until then, tokenized funds will continue to reflect the money-market sleeve without saying much about demand further out the curve. Credit has more activity, but the book still combines digital-asset financing with lending to the real economy, making it difficult to read without a cleaner split between the two and better identification of borrowers.

Commodities provide a good example of both. Tokenized gold tracks the broader accumulation of the metal, with ounces outstanding rising faster than the gold price, while oil trading through perpetuals and event markets reflects the geopolitical tensions shaping the physical market. These onchain markets offer a distinct venue to trade and express views, particularly when the outlook in traditional markets is so unsettled that even a major house such as J.P. Morgan has withdrawn its baseline oil-price forecast.

Equities show a different kind of divergence, driven largely by access and demand. Investors are seeking exposure to AI names and pre-IPO companies that can be difficult to access through traditional markets. Onchain venues bring these exposures together through both tokenized shares and synthetic products, allowing securities that are otherwise separated by geography or market structure to trade in the same environment. That helps explain why onchain equity markets can look less regionally siloed than their underlying markets.

The research task from here is less about counting how much has been tokenized and more about keeping that comparison with the underlying markets. The useful question is where these products simply reproduce existing activity, and where they begin to show something the underlying market does not.

COPYRIGHT © 2026 DUNE

Methodology

Data

The analysis is built on Dune's RWA dataset, with event-market figures from Dune's prediction-market dataset. Cutoff date is 31 August 2026 unless stated.

What is counted

We cover four asset classes: cash equivalents, credit, commodities and equities. For each, we include tokenized claims and, where available, synthetic exposure through Hyperliquid perpetuals and event markets on Kalshi and Polymarket. Supply is the dollar value of tokens outstanding. The one exception is xStocks, where we use circulating supply: the issuer mints ahead of demand and holds the balance in its own wallets, so total supply counts a large amount that has never reached an investor. Perpetual open interest is one-sided. Hyperliquid reports both sides of each contract, so we halve its figure. Perpetual volume is already one-sided. Spot volume counts each trade once on the tokenized leg, across decentralized exchanges and onchain trading venues. Perpetual volume and open interest are notional exposure, the face value of positions rather than the capital committed to them. Spot volume figures are value exchanged. Prediction-market figures are USD traded value on the taker side: for each matched trade, the contracts traded multiplied by the price paid, counted once. Contract counts are a separate measure of activity and are not converted to dollars, since a contract's $1 settlement value is a potential payout rather than an amount exchanged.

Coverage

Products are included where the underlying data supports the relevant measure. Assets without a published price cannot carry a yield; those without onchain transfer history cannot be measured for trading. Where a figure covers only part of a class, the text says so.

Yields

Yields are realised NAV returns, not advertised rates, over a 90-day trailing window, annualised. This covers the money-fund yields in section 2 and the credit yield ranges in section 4. The credit figures quoted in the text are the median of the last 30 daily prints of that 90-day yield, so one irregular NAV does not set the number; the credit yield chart uses a 30-day window instead, so the series can move inside a month. Where a fund pays by minting tokens, we measure balance growth among holders who neither subscribed nor redeemed, over complete payout cycles. BUIDL uses the issuer-reported yield, the only all-chain figure. The money-fund benchmark is the 13-week bill at the start of each 90-day window.

Definitions

Geography in the Equities chapter is based on company domicile, not listing venue. SK Hynix therefore counts as Korea for both its Seoul share and Nasdaq ADS. Collateral use is measured two ways. Section 1 reads holder labels on the token side; section 6 reads each protocol's own records. The two cover slightly different sets, so the totals differ. DEX liquidity is the value of tokens held in pool contracts. On concentrated-liquidity venues, some capital sits outside the current trading range. An address is not an investor. Custodians can represent many clients, while one institution can use multiple addresses. Holder counts therefore describe accounts, not people.

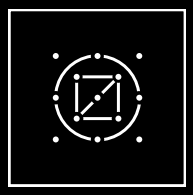

Disclaimer

This report is published by Dune for information purposes only. It is not investment, legal, or tax advice. It is not an offer, solicitation, or recommendation to buy, sell, or hold any security, token, fund, or other asset. Naming or comparing a product, issuer, or venue does not mean Dune endorses it. Yields and other figures are historical, and past performance does not indicate future results. Figures come from public blockchain data, parsed and structured by Dune, and from the third-party sources cited. They are as of 31 August 2026 unless stated otherwise. Dune is the industry standard for onchain data

Structured, institutional-grade blockchain datasets across 130+ chains, delivered into the stack you already run. Trusted by 1,000+ industry leaders, including Visa, WisdomTree, S&P, and UBS.

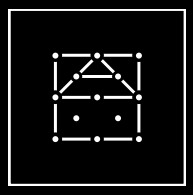

Stablecoins

Every stablecoin transfer classified by economic intent and every holder labeled by venue type, across 38 chains and 200+ stablecoins.

Payments

Transfer-level onchain payment records across card transactions, agentic settlements, and stablecoin commerce.

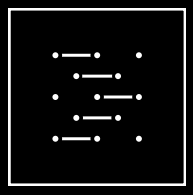

Real-World Assets

The deepest record of tokenized assets onchain: supply, issuers, terms, holders, and every transfer and trade, plus perpetuals exposure.

Prediction Markets

Every Kalshi and Polymarket market in one dataset, normalized into probability time series. Trade-level data, hourly price history, and resolution outcomes.

Dune Market Data Feeds

Real-time onchain market data for spot and perpetuals markets. Every trade on 200+ decentralized venues, delivered in about a second.
